

## \* Toric Code

→ A CSS code

→ It's a family of codes, one for each positive integer  $\geq 2$

→ All stabilizer generators have weight 4

→ It has geometric locality → Each stabilizer generator measures qubits only near it

→ It has increasingly large distance, can tolerate relatively high error rate

### → Toric Code Description

Consider  $L \times L$  lattice for  $L \geq 8 \rightarrow L \geq 2$

Torus / Doughnut

→ Bottom dotted line is the same as top line,  
Right dotted line is the same as left line

→ Qubits are placed on the edges, indication by solid circles

↳  $2L^2$  qubits

→ we obtain stabilizer generators by,

For each tile we tensor  $Z$  on the 4 edge qubits and  $I$  on all other

$$I \otimes I \otimes Z \otimes Z \otimes Z \otimes Z \otimes I \otimes I$$

↳ we can choose how to order qubits

→ For each vertex we tensor  $X$  on the 4 edge qubits,  $I$  on all other

→ ex. →

$$Z \otimes Z \otimes Z \otimes Z \otimes I \otimes I \otimes I \otimes I$$

$$I \otimes Z \otimes Z \otimes Z \otimes I \otimes Z \otimes I \otimes I$$

$$Z \otimes I \otimes I \otimes I \otimes Z \otimes I \otimes Z \otimes Z$$

$$I \otimes Z \otimes I \otimes I \otimes I \otimes Z \otimes Z \otimes Z$$

$$X \otimes X \otimes X \otimes I \otimes I \otimes I \otimes I \otimes X$$

$$X \otimes X \otimes I \otimes X \otimes I \otimes I \otimes I \otimes X$$

$$X \otimes X \otimes X \otimes I \otimes I \otimes I \otimes X \otimes I$$

$$I \otimes I \otimes X \otimes I \otimes X \otimes X \otimes X \otimes I$$

$$I \otimes I \otimes I \otimes X \otimes X \otimes X \otimes I \otimes X$$

$$I \otimes I \otimes X \otimes I \otimes X \otimes X \otimes I \otimes X$$

$$X \otimes X \otimes X \otimes I \otimes I \otimes I \otimes X \otimes I$$

## \* Correcting Errors

when we get the  $-1$  outcomes, we apply  $X$  correction gates along the shortest path

→ Forms closed loop

Errors that go around the torus aren't corrected

—

→ Actual error path

—

→ Shortest Path

$X$  → Qubit corrected by  $X$  gates

→ For more than  $Z$   $-1$  outcomes, we can use Blossom algorithm (classical algorithm) to find minimum-weight perfect matching paths

→ It works well below a noise rate of  $\sim 10\%$

↓  
Detecting, correcting  $Z$  errors is analogous with  $X$  errors, we use  $X$ -sg instead of  $Z$ -sg

→ When error forms closed loop, we can't detect it

↳ However, it isn't actually an error as it is in the stabilizer

↓  
It can be obtained by multiplying adjacent  $X$ -sg forming a closed loop

→ Closed loops of this form, that go around the torus, can't be detected

→ Min weight  $\rightarrow L$  → distance

Toric Code  $\rightarrow [[2L^2, 2, L]]$  code

↓  
Topological Quantum Error Correcting Code

# \* Detecting errors

- → unaffected qubit
- → qubit affected by X error

□ → +1 measurement outcome  
▨ → -1 measurement outcome

X-error → corrected by Z-sg

↳ Z-sg measures parity of 4 qubits

+1 doesn't mean no error always

In case of multiple X errors,

• unaffected qubits aren't shown

↳ Code gives -1 outcomes for Z-sg at endpoints of the chain

↳ It can be detected, corrected

$XXIXIX$

$XXXIXIX$

→ we can see, all stabilizer generators commute each other

$$\prod (Z-sg) \cdot \prod (X-sg) = I$$

↳ All  $Z, X$  repeat 2 times in 2 squares

$$\downarrow$$

$$(Z-sg)_b = \prod_{a \neq b} (Z-sg)_a \quad (X-sg)_b = \prod_{a \neq b} (X-sg)_a$$

↳ If we remove 1  $Z-sg, X-sg$  they form minimal generating set

↳ That 1 can be expressed as the product of all others, adds no extra information

so, we have  $L^2 - 1$  sg of each type,  $2L^2 - 2$  in total

$$\text{Total qubits} = 2L^2$$

$$\text{Toric code encodes} \rightarrow 2L^2 - (2L^2 - 2) = 2 \text{ qubits}$$
